1 | Question 1 - Models for Binary Vectors

1.1 Question 1.(a)

We dispose of a data set of N binary images. Each of these images has a finite number of D discrete pixels, each taking a value 0 or 1, but not in between. The Multivariate Gaussian distribution is defined on the domain $x \in \mathbb{R}^k$, and its data type is continuous and unbounded. Compared to our data which is discrete and bounded $(x_d^{(n)} \in \{0,1\})$, then the Multivariate Gaussian distribution is not suited for the data set of images.

1.2 Question 1.(b)

We assume the images were modelled as independently and identically distributed (**iid**) samples from a D-dimensional multivariate Bernoulli distribution with parameter vector $\mathbf{p} = (p_1, ..., p_D)$:

$$P(\mathbf{x}^{(\mathbf{n})}|\mathbf{p}) = \prod_{d=1}^{D} p_d^{x_d^{(n)}} (1 - p_d)^{1 - x_d^{(n)}} \qquad n \in 1, ..., N$$
(1.1)

where \mathbf{x} , \mathbf{p} are D-dimensional vectors.

The equation for the likelihood of \mathbf{p} is calculated as:

$$P(\mathbf{x}|\mathbf{p}) = \prod_{n=1}^{N} P(\mathbf{x}^{(n)}|\mathbf{p}) = \prod_{n=1}^{N} \prod_{d=1}^{D} p_d^{x_d^{(n)}} (1 - p_d)^{1 - x_d^{(n)}}$$
(1.2)

To obtain the log-likelihood, we take the log of the expression, yielding:

$$\mathcal{L} = \log \prod_{n=1}^{N} \prod_{d=1}^{D} p_d^{x_d^{(n)}} (1 - p_d)^{1 - x_d^{(n)}}$$

$$\mathcal{L} = \sum_{n=1}^{N} \sum_{d=1}^{D} p_d^{x_d^{(n)}} (1 - p_d)^{1 - x_d^{(n)}}$$

$$\mathcal{L} = \sum_{n=1}^{N} \sum_{d=1}^{D} x_d^{(n)} \log p_d + (1 - x_d^{(n)}) \log (1 - p_d)$$
(1.3)

To evaluate the Maximum Likelihood, we need to find the maximum of that function:

$$\frac{\partial \mathcal{L}(p)}{\partial p_d} = 0$$

Equivalent to:

$$\sum_{n=1}^{N} \left(\frac{x_d^{(n)}}{p_d} - \frac{(1 - x_d^{(n)})}{1 - p_d} \right) = 0$$

$$\sum_{n=1}^{N} \left(\frac{x_d^{(n)} (1 - p_d) - p_d (1 - x^{(n)})}{p_d (1 - p_d)} \right) = 0$$

Which is achieved when the numerator is equal to 0:

$$\sum_{n=1}^{N} x_d^{(n)} (1 - p_d) - p_d (1 - x^{(n)}) = 0$$

$$\sum_{n=1}^{N} (x_d^{(n)} - p_d) = 0$$

$$\sum_{n=1}^{N} x_d^{(n)} = \sum_{n=1}^{N} p_d$$

And since p_d does not depend on N, we obtain the Maximum Likelihood (ML) estimation of p_d , denoted as \hat{p}_d^{ML} :

$$\sum_{n=1}^{N} x_d^{(n)} = N p_d$$

$$\hat{p}_d^{ML} = \frac{1}{N} \sum_{n=1}^{N} x^{(n)} \tag{1.4}$$

Generalizing for all values of d since the pixels are assumed to be independent, we get:

$$\hat{\mathbf{p}}^{\mathbf{ML}} = \frac{1}{N} \sum_{n=1}^{N} \mathbf{x}^{(n)} \tag{1.5}$$

1.3 Question 1.(c)

We assume independent Beta priors on the parameters p_d :

$$P(p_d) = \frac{1}{B(\alpha, \beta)} p_d^{\alpha - 1} (1 - p_d)^{\beta - 1}$$
(1.6)

And:

$$P(\mathbf{p}) = \prod_{d} P(p_d) \tag{1.7}$$

To find the MAP estimator of p, we firstly use Bayes Rule:

$$P(\mathbf{p}|\mathbf{x}) = \frac{P(\mathbf{x}|\mathbf{p})P(\mathbf{p})}{P(\mathbf{x})}$$
(1.8)

Combining the expressions, we get:

$$P(\mathbf{p}|\mathbf{x}) = \frac{\prod_{n=1}^{N} \prod_{d=1}^{D} p_d^{x_d^{(n)}} (1 - p_d)^{1 - x_d^{(n)}} \prod_{d=1}^{D} P(p_d)}{P(\mathbf{x})}$$
(1.9)

The expression is hard to compute, but, since P(x) does not depend on d, we can state the following:

$$P(\mathbf{p}|\mathbf{x}) \propto p_d^{x_d^{(n)}} (1 - p_d)^{1 - x_d^{(n)}}$$
 (1.10)

Taking the log of the expression:

$$\log P(\mathbf{p}|\mathbf{x}) = \sum_{n=1}^{N} \sum_{d=1}^{D} \left(x_d^{(n)} \log p_d + (1 - x_d^{(n)}) \log (1 - p_d) \right)$$
$$+ \sum_{d=1}^{D} \left(\log(p_d)(\alpha - 1) + (\beta - 1) \log (1 - p_d) \right) - D \log B(\alpha, \beta)$$

We need to find the maximum of this expression. Differentiating with respect to p_d , we get:

$$\frac{\partial \log P(\mathbf{p}|\mathbf{x})}{\partial p_d} = \sum_{n=1}^{N} \left(x_d^{(n)} \frac{1}{p_d} + (1 - x_d^{(n)}) \frac{-1}{1 - p_d} \right) + \frac{(\alpha - 1)}{p_d} - \frac{\beta - 1}{1 - p_d}$$
(1.11)

Because the Beta function term is independent of d.

$$\frac{\partial \log P(\mathbf{p}|\mathbf{x})}{\partial p_d} = \sum_{n=1}^{N} \left(\frac{x_d^{(n)} (1 - p_d) - (1 - x_d^{(n)}) p_d}{p_d (1 - p_d)} \right) + \frac{(\alpha - 1)(1 - p_d) - (\beta - 1) p_d}{p_d (1 - p_d)}$$

$$= \sum_{n=1}^{N} \left(\frac{x_d^{(n)} - p_d - x_d^{(n)} p_d + x_d^{(n)} p_d}{p_d (1 - p_d)} \right) + \frac{\alpha - 1 - \alpha p_d + p_d - \beta p_d + p_d}{p_d (1 - p_d)}$$

$$\frac{\partial \log P(\mathbf{p}|\mathbf{x})}{\partial p_d} = \frac{\sum_{n=1}^{N} \left(x_d^{(n)} - p_d \right) + \alpha - 1 + p_d (2 - \alpha - \beta)}{p_d (1 - p_d)} \tag{1.12}$$

Making this expression equal to 0:

$$\frac{\partial \log P(\mathbf{p}|\mathbf{x})}{\partial p_d} = 0 \tag{1.13}$$

Equivalent to:

$$\sum_{n=1}^{N} \left(x_d^{(n)} - p_d \right) + \alpha - 1 + p_d (2 - \alpha - \beta) = 0$$
 (1.14)

$$\sum_{n=1}^{N} (x_d^{(n)}) - Np_d + \alpha - 1 + p_d(2 - \alpha - \beta) = 0$$

$$p_d(N + \alpha + \beta - 2) = \sum_{n=1}^{N} (x_d^{(n)}) + \alpha - 1$$

$$\hat{p}_d^{MAP} = \frac{\sum_{n=1}^{N} (x_d^{(n)}) + \alpha - 1}{N + \alpha + \beta - 2}$$
(1.15)

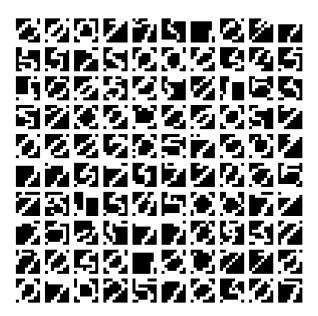

Figure 1.1: Original data from binarydigits.txt, used for training

And thus, generalizing for **p**, we obtain the Maximum A Posteriori (MAP) expression of **p**:

$$\hat{\mathbf{p}}^{MAP} = \frac{\sum_{n=1}^{N} (x^{(n)}) + \alpha - 1}{N + \alpha + \beta - 2}$$
(1.16)

1.4 Question 1.(d)

The original data contains N=100 image, each made of D=64 pixels and stored in an $N\times D$ matrix. Rearranging the pixels, Figure 1.1 shows the original data from the binarydigits.txt file, and displaying them as an 8×8 image, which was displayed by readapting the code from bindigit.py.

After executing the code to learn the ML parameters of the multivariate Bernoulli from the dataset, the obtained ML parameters are shown in Figure 1.2(a). Those parameters are displayed as an 8×8 image. The code for the execution can be found below.

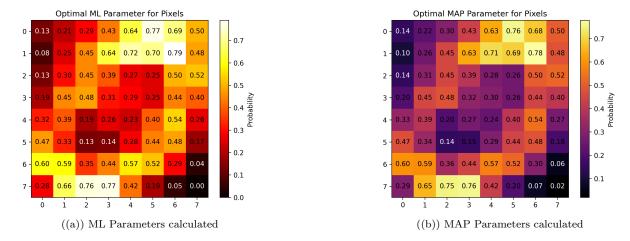

Figure 1.2: ML and MAP Parameters

Listing 1: Code - Q1.(d)

```
import numpy as np
1
    from matplotlib import pyplot as plt
2
    # Loading the training data
    def load_binarydigits(filename='binarydigits.txt'):
5

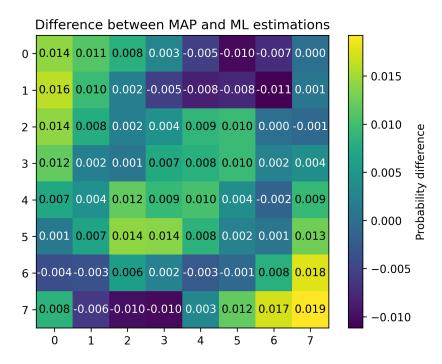

Figure 1.3: Substracting ML parameters to MAP parameters: $\hat{\mathbf{p}}^{MAP} - \hat{\mathbf{p}}^{ML}$

1.5 Question 1.(e)

Modifying the code built for the previous question, we obtain the MAP parameters displayed in Figure 1.2(b), which appear different if we look closely to the displayed numbers on each tile and compare them with that of the ML parameters. For the difference to be more visible, Figure 1.3 shows the difference between MAP and ML parameters, calculated as $\hat{\mathbf{p}}^{MAP} - \hat{\mathbf{p}}^{ML1}$. It provides a better visual of the difference between these two estimations.

The new code is displayed below.

The new learned parameters are better than the ML estimate due to the limited amount of data. If we had more data, the MAP estimate would yield the same result as the ML estimate. Having the MAP estimate permits the model to not assume some pixels are 1's and others are 0's by defaults, because it takes into account what it has seen on the prior.

 $^{^{1}}$ Why the difference, and not the quotient: some entries are 0, the computer will display an error in such case.

2 | Question 2 - Model selection

We would like to find the expressions needed to calculate the relative probabilities of three different models regarding our binary data images.

2.1 Question 2.(a)

For this model (named *Model 1*), we assume all D components are generated from a Bernoulli distribution with identical $p_d = 0.5$. Thus, the probability of data x given $p_d = 0.5$ is:

$$P_{1}(x^{n}|\mathbf{p} = [p_{d}, ..., p_{d}]^{T}, p_{d} = 0.5) = \prod_{i=1}^{D} p_{d}^{x_{i}^{(n)}} (1 - p_{d})^{1 - x_{i}^{(n)}}$$

$$= \prod_{d=i}^{D} 0.5^{x_{i}^{(n)}} (1 - 0.5)^{1 - x_{i}^{(n)}}$$

$$= \prod_{i=1}^{D} 0.5^{x_{i}^{(n)} + 1 - x_{i}^{(n)}}$$

$$= \prod_{i=1}^{D} 0.5$$

$$P_{1}(x^{(n)}|\mathbf{p} = [p_{d}, ..., p_{d}]^{T}, p_{d} = 0.5) = 0.5^{D}$$
(2.2)

Thus, for the entire dataset, since all images are considered to be independent and identically sampled (iid):

$$P_{1}(\mathbf{x}|\mathbf{p} = [p_{d}, ..., p_{d}]^{T}, p_{d} = 0.5) = \prod_{n=1}^{N} P_{1}(x^{(n)}|\mathbf{p} = [p_{d}, ..., p_{d}]^{T}, p_{d} = 0.5)$$

$$= \prod_{n=1}^{N} 0.5^{D}$$
(2.3)

$$P_1(\mathbf{x}|\mathbf{p} = [p_d, ..., p_d]^T, p_d = 0.5) = 0.5^{N \times D}$$
 (2.4)

For each model, the likelihood of the data \mathbf{x} given the model i is given by:

$$P(\mathbf{x}|\text{Model }i) = \int_0^1 P_i(\mathbf{x}|\mathbf{p})P(\mathbf{p})dp$$
 (2.5)

Where $P(\mathbf{p})$ is known to be uniform for all unknown probabilities. In the case of Model 1, we know the prior probability and it is equal to 1 (no probability of having something else than $p_d = 0.5$). Therefore:

$$P(\mathbf{x}|\text{Model 1}) = \int_0^1 P_1(\mathbf{x}|\mathbf{p}) d\mathbf{p}$$

$$= \int_0^1 0.5^{N \times D} d\mathbf{p}$$

$$= 0.5^{N \times D} \int_0^1 d\mathbf{p}$$
(2.6)

$$P(\mathbf{x}|\text{Model 1}) = 0.5^{N \times D} \tag{2.7}$$

2.2 Question 2.(b)

For this model (named *Model 2*), we assume all D components are generated from Bernoulli distributions with unknown but identical p_d . The probability $P_2(x^{(n)}|\mathbf{p} = [p_d, ..., p_d]^T)$ is:

$$P_2(x^{(n)}|\mathbf{p}) = \prod_{i=1}^{D} p_d^{x_i^{(n)}} (1 - p_d)^{1 - x_i^{(n)}}$$
(2.8)

Leading to:

$$P_2(x^{(n)}|\mathbf{p}) = p_d^{\sum_{i=1}^D x_i^{(n)}} (1 - p_d)^{\sum_{d=1}^D (1 - x_i^{(n)})}$$
(2.9)

N.B. notice we changed the indice of the product, to avoid confusion. For the entire image dataset, we obtain:

$$P_2(\mathbf{x}|\mathbf{p}) = \prod_{n=1}^{N} P_2(x^{(n)}|\mathbf{p})$$
 (2.10)

Which we calculated before:

$$= \prod_{n=1}^{N} p_d^{\sum_{i=1}^{D} x_i^{(n)}} (1 - p_d)^{\sum_{d=1}^{D} (1 - x_i^{(n)})}$$

$$= p_d^{\sum_{n=1}^{N} \sum_{i=1}^{D} x_i^{(n)}} (1 - p_d)^{\sum_{n=1}^{N} \sum_{d=1}^{D} (1 - x_i^{(n)})}$$

Thus, as for Model 1, to obtain the likelihood of Model 2:

$$P(\mathbf{x}|\text{Model 2}) = \int_0^1 P_2(\mathbf{x}|\mathbf{p})P(\mathbf{p})d\mathbf{p}$$
 (2.11)

And since we assumed a uniform prior because p_d is unknown, therefore it becomes:

$$P(\mathbf{x}|\text{Model 2}) = \int_0^1 P_2(\mathbf{x}|\mathbf{p}) dp_d$$

$$(2.12)$$

$$= \int_0^1 p_d^{\sum_{n=1}^N \sum_{i=1}^D x_i^{(n)}} (1-p_d)^{\sum_{n=1}^N \sum_{d=1}^D (1-x_i^{(n)})} dp_d$$

And since integrating a Binomial function (parameters over the interval [0,1] is the same as evaluating the Beta function:

$$B(\alpha, \beta) = \int_0^1 p^{\alpha - 1} (1 - p)^{\beta - 1} dp$$

Then, by identification:

$$P(\mathbf{x}|\text{Model 2}) = B\left(1 + \sum_{n=1}^{N} \sum_{i=1}^{D} x_i^{(n)}, 1 + \sum_{n=1}^{N} \sum_{i=1}^{D} (1 - x_i^{(n)})\right)$$

Moreover, the Beta function, if its parameters are integers, can be evaluated as:

$$Beta(i,j) = \frac{(i-1)!(j-1)!}{(i+j-1)!}$$

Since $x_i^{(n)}$'s only take 0's or 1's as values, we can deduce their sums will be integers and therefore:

$$P(\mathbf{x}|\text{Model 2}) = \frac{\left(\sum_{n=1}^{N} \sum_{i=1}^{D} x_i^{(n)}\right)! \left(\sum_{n=1}^{N} \sum_{i=1}^{D} (1 - x_i^{(n)})\right)!}{\left(\sum_{n=1}^{N} \sum_{i=1}^{D} x_i^{(n)} + \sum_{n=1}^{N} \sum_{i=1}^{D} (1 - x_i^{(n)}) + 1\right)!}$$
(2.13)

Finally, we can rapidly develop the second double sum to obtain:

$$P(\mathbf{x}|\text{Model 2}) = \frac{\left(\sum_{n=1}^{N} \sum_{i=1}^{D} x_i^{(n)}\right)! \left(N \times D + \sum_{n=1}^{N} \sum_{i=1}^{D} (-x_i^{(n)})\right)!}{\left(\sum_{n=1}^{N} \sum_{i=1}^{D} x_i^{(n)} + N \times D + \sum_{n=1}^{N} \sum_{i=1}^{D} (-x_i^{(n)}) + 1\right)!}$$

Leading to the final expression:

$$P(\mathbf{x}|\text{Model 2}) = \frac{\left(\sum_{n=1}^{N} \sum_{i=1}^{D} x_i^{(n)}\right)! \left(N \times D - \sum_{n=1}^{N} \sum_{i=1}^{D} (x_i^{(n)})\right)!}{(N \times D + 1)!}$$
(2.14)

A note on implementation After implementing and testing the model's probability, the difficulty of implementing large factorial functions (displaying errors due to too intensive computation) led to finally implement them using the log of Beta function formula. This have been done using betaln() function from scipy.special library.

2.3 Question 2.(c)

We now consider a model (named *Model 3*) with each component being Bernoulli distributed, with a separate and unknown p_d . We therefore have:

$$P_3(x^{(n)}|\mathbf{p}) = \prod_{d=1}^{D} p_d^{x_d^{(n)}} (1 - p_d)^{(1 - x_d^{(n)})}$$
(2.15)

$$P_3(\mathbf{x}|\mathbf{p}) = \prod_{n=1}^{N} \prod_{d=1}^{D} p_d^{x_d^{(n)}} (1 - p_d)^{(1 - x_d^{(n)})}$$
(2.16)

For Model 3's likelihood, it is obtained similarly to that of Model 2:

$$P(\mathbf{x}|\text{Model }3) = \int_0^1 P_3(\mathbf{x}|\mathbf{p})P(\mathbf{p})d\mathbf{p}$$
 (2.17)

But since each component has a separate unknown p_d , still with uniform prior, we get:

$$P(\mathbf{x}|\text{Model }3) = \int_0^1 \dots \int_0^1 P_3(\mathbf{x}|\mathbf{p}) dp_1 \dots dp_D$$
(2.18)

Equivalent to:

$$P(\mathbf{x}|\text{Model 3}) = \int_0^1 \dots \int_0^1 \prod_{n=1}^N \prod_{d=1}^D p_d^{x_d^{(n)}} (1 - p_d)^{(1 - x_d^{(n)})} dp_1 \dots dp_D$$

Which can be separated into (since all p_d are independent and separate):

$$P(\mathbf{x}|\text{Model }3) = \prod_{d=1}^{D} \left(\int_{0}^{1} \prod_{n=1}^{N} p_{d}^{x_{d}^{(n)}} (1 - p_{d})^{(1 - x_{d}^{(n)})} dp_{d} \right)$$
$$= \prod_{d=1}^{D} \left(\int_{0}^{1} p_{d}^{\sum_{n=1}^{N} x_{d}^{(n)}} (1 - p_{d})^{\sum_{n=1}^{N} (1 - x_{d}^{(n)})} dp_{d} \right)$$

Leading to:

$$P(\mathbf{x}|\text{Model 3}) = \prod_{d=1}^{D} B\left(1 + \sum_{n=1}^{N} x_d^{(n)}, 1 + \sum_{n=1}^{N} (1 - x_d^{(n)})\right)$$

$$P(\mathbf{x}|\text{Model 3}) = \prod_{d=1}^{D} \frac{\left(\sum_{n=1}^{N} x_d^{(n)}\right)! \left(\sum_{n=1}^{N} (1 - x_d^{(n)})\right)!}{\left(\sum_{n=1}^{N} x_d^{(n)} + \sum_{n=1}^{N} (1 - x_d^{(n)}) + 1\right)!}$$
(2.19)

And, after manipulations, leads us to the final expression:

$$P(\mathbf{x}|\text{Model 3}) = \prod_{d=1}^{D} \frac{\left(\sum_{n=1}^{N} x_d^{(n)}\right)! \left(\sum_{n=1}^{N} (1 - x_d^{(n)})\right)!}{(N+1)!}$$

$$P(\mathbf{x}|\text{Model 3}) = \frac{1}{D(N+1)!} \times \prod_{d=1}^{D} \left(\sum_{n=1}^{N} x_d^{(n)}\right)! \left(\sum_{n=1}^{N} (1 - x_d^{(n)})\right)!$$
(2.20)

A note on implementation Again, similarly to Model 2's implementation, the difficulty of implementing large factorial functions for Model 3 led to finally implement them using the log of Beta function formula. This have been done using *betaln()* function from *scipy.special* library (once again).

2.4 Question 2. Answer

We assume all models 1, 2 and 3 are equally likely *a priori*, and their prior distributions to be uniform for any unknown probabilities. We would like to find the posterior probabilities of each of the three models.

From Bayes Rule, $i \in 1, 2, 3$:

$$P(\text{Model } i|\mathbf{x}) = \frac{P(\mathbf{x}|\text{Model } i)P(\text{Model } i)}{P(\mathbf{x})}$$
(2.21)

Since all three models are equally likely a priori:

$$P(\text{Model } 1) = P(\text{Model } 2) = P(\text{Model } 3) = \frac{1}{3}$$

And using:

$$P(\mathbf{x}) = P(\mathbf{x}, \text{Model } 1) + P(\mathbf{x}, \text{Model } 2) + P(\mathbf{x}, \text{Model } 3)$$

$$P(\mathbf{x}) = P(\mathbf{x}|\text{Model } 1)P(\text{Model } 1) + P(\mathbf{x}|\text{Model } 2)P(\text{Model } 2) + P(\mathbf{x}|\text{Model } 3)P(\text{Model } 3)$$

Leading to:

$$P(\mathbf{x}) = \frac{1}{3} \left(P(\mathbf{x}|\text{Model 1}) + P(\mathbf{x}|\text{Model 2}) + P(\mathbf{x}|\text{Model 3}) \right)$$
(2.22)

We therefore get for Model 1:

$$P(\text{Model } 1|\mathbf{x}) = \frac{P(\mathbf{x}|\text{Model } 1)P(\text{Model } 1)}{P(\mathbf{x})}$$

Simplifying to (due to equally likely models):

$$P(\text{Model 1}|\mathbf{x}) = \frac{P(\mathbf{x}|\text{Model 1}) \times \frac{1}{3}}{\frac{1}{3} \left(P(\mathbf{x}|\text{Model 1}) + P(\mathbf{x}|\text{Model 2}) + P(\mathbf{x}|\text{Model 3}) \right)}$$

Permits us to obtain the MAP equations for Model 1:

$$P(\text{Model 1}|\mathbf{x}) = \frac{P(\mathbf{x}|\text{Model 1})}{P(\mathbf{x}|\text{Model 1}) + P(\mathbf{x}|\text{Model 2}) + P(\mathbf{x}|\text{Model 3})}$$
(2.23)

Similarly for models 2 and 3:

$$P(\text{Model 2}|\mathbf{x}) = \frac{P(\mathbf{x}|\text{Model 3})}{P(\mathbf{x}|\text{Model 1}) + P(\mathbf{x}|\text{Model 2}) + P(\mathbf{x}|\text{Model 3})}$$
(2.24)

And

$$P(\text{Model } 3|\mathbf{x}) = \frac{P(\mathbf{x}|\text{Model } 3)}{P(\mathbf{x}|\text{Model } 1) + P(\mathbf{x}|\text{Model } 2) + P(\mathbf{x}|\text{Model } 3)}$$
(2.25)

Log of these probabilities To be easily implemented, the function betaln() was the simplest option. However, it is not explicit in the formulas above how they relate. Therefore, for each model i, the probability can be expressed:

$$\log P(\text{Model } i|\mathbf{x}) = \log P(\mathbf{x}|\text{Model } i) - \log \left(P(\mathbf{x}|\text{Model } 1) + P(\mathbf{x}|\text{Model } 2) + P(\mathbf{x}|\text{Model } 3)\right)$$

 $\log P(\text{Model } i|\mathbf{x}) = \log P(\mathbf{x}|\text{Model } i) - \log (\exp\{\log P(\mathbf{x}|\text{Model } 1)\} + \exp\{P(\mathbf{x}|\text{Model } 2)\} + \exp\{P(\mathbf{x}|\text{Model } 3)\})$

$$\log P(\text{Model } i|\mathbf{x}) = \log P(\mathbf{x}|\text{Model } i) - \log \left(\sum_{j=1}^{3} \exp\{\log P(\mathbf{x}|\text{Model } j)\} \right)$$
 (2.26)

For which the second argument can easily be calculated using the logsum exp() function from scipy.special library.

From the code used, we obtained the following results for the different models log likelihood, and for their probability (**not** in log), all summed in Table 2.1.

Model 1	Model 2	Model 3
-4.436×10^{3} 9.143×10^{-255}	-4.284×10^3 1.434×10^{-188}	-3.851×10^{3} $1.0 - 9.143 \times 10^{-255} - 1.434 \times 10^{-188}$

Table 2.1: Log Likelihood and MAP estimations of each model

Interpretation What we can deduce from these results is that it is highly likely the data follows a model with each component being Bernoulli distributed with a separate and unknown p_d , compared to Models 1 and 2. This makes sense since our data is diverse and hence make it impossible to follow Model 1.

3 | Question 3 - EM for Binary Data

3.1 Question 3.(a)

We consider a mixture of K multivariate Bernoulli distributions. We use the parameters $\pi_1, ..., \pi_K$ to denote the mixing proportions, each comprised between 0 and 1 (0 $\leq \pi_k \leq$ 1) and all summing to 1 $(\sum_{k=1}^K \pi_k = 1)$.

We define the parameters vectors as $\mathbf{p}_k = (p_{k,1}, ..., p_{k,D})$, and the matrix P as:

$$\mathbf{P} = [\mathbf{p}_1, ..., \mathbf{p}_K]^T \tag{3.1}$$

Where each $p_{k,d}$ is defined as $0 \le p_{k,d} \le 1$, $k \in [0; K]$, $d \in [0; D]$.

Each model is independent and identically distributed (Assumption 1), and pixels are independent of each other within each component distribution (Assumption 2).

Each of the N images (with index n), assumed to be independent (Assumption 3) are defined as:

$$x^{(n)} = (x_1^{(n)}, ..., x_D^{(n)}) \qquad \quad x_d^{(n)} \in \{0, 1\}, \quad d \in [0; D], \quad n \in [0; N]$$

Once all these information have been made clear, we can make the following expression, due to Assumption 2:

$$p(x^{(n)}|k) = \prod_{d=1}^{D} p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}}$$
(3.3)

Leading to the following expression for the likelihood of the mixture element π_k , which is the product between its proportion and its likelihood:

$$p(x^{(n)}|\pi_k) = \pi_k \times p(x^{(n)}|k)$$
 (3.4)

$$p(x^{(n)}|\pi_k) = \pi_k \prod_{d=1}^{D} p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}}$$
(3.5)

From that, the probability of x_i given by the set of Multivariate Bernoulli distribution used in the mixture is:

$$p(x^{(n)}|\boldsymbol{\pi}) = \sum_{k=1}^{K} p(x^{(n)}|\pi_k)$$
(3.6)

$$p(x^{(n)}|\boldsymbol{\pi}) = \sum_{k=1}^{K} \pi_k \prod_{d=1}^{D} p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}}$$
(3.7)

Thus, for the whole set of images, the likelihood is given by:

$$p(\mathbf{x}|\boldsymbol{\pi}) = p(x^{(1)}, ..., x^{(N)}|\boldsymbol{\pi})$$
(3.8)

And since Assumption 3:

$$p(\mathbf{x}|\boldsymbol{\pi}) = \prod_{n=1}^{N} p(x^{(n)}|\boldsymbol{\pi})$$

$$p(\mathbf{x}|\boldsymbol{\pi}) = \prod_{n=1}^{N} \left(\sum_{k=1}^{K} \pi_k \prod_{d=1}^{D} p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}} \right)$$
(3.9)

Taking the log of this expression, we get the log likelihood expression:

Log Likelihood = $\log(p(\mathbf{x}|\boldsymbol{\pi}))$

$$\mathbf{Log\ Likelihood} = \sum_{n=1}^{N} \log \left(\sum_{k=1}^{K} \pi_k \prod_{d=1}^{D} p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}} \right)$$
(3.10)

For simplicity, we can introduce some matrix notations:

$$\mathbf{X} = [x^{(1)}, ..., x^{(N)}]^T \tag{3.11}$$

which will be a matrix of size $N \times D$. We also notice the following:

$$p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}} = \exp\left\{\log p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}}\right\}$$
$$= \exp\left\{x_d^{(n)} \log p_{k,d} + (1 - x_d^{(n)}) \log(1 - p_{k,d})\right\}$$

Thus, replacing in 3.7, we get:

$$p(x^{(n)}|\boldsymbol{\pi}) = \sum_{k=1}^{K} \pi_k \prod_{d=1}^{D} p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}}$$

$$= \sum_{k=1}^{K} \pi_k \prod_{d=1}^{D} \exp\left\{x_d^{(n)} \log p_{k,d} + (1 - x_d^{(n)}) \log(1 - p_{k,d})\right\}$$

$$p(x^{(n)}|\boldsymbol{\pi}) = \sum_{k=1}^{K} \pi_k \exp\left\{\sum_{d=1}^{D} \left(x_d^{(n)} \log p_{k,d} + (1 - x_d^{(n)}) \log(1 - p_{k,d})\right)\right\}$$
(3.12)

And using now matrices **X** and **P** of dimensions $N \times K$ and $K \times D$ respectively:

$$p(x^{(n)}|\boldsymbol{\pi}) = \sum_{k=1}^{K} \pi_k \exp\left\{ (x^{(n)})^T \log(\mathbf{p}_k) + (1 - x^{(n)})^T \log(1 - \mathbf{p}_k) \right\}$$
(3.13)

Generalizing for the log likelihood 12 :

$$\log p(\mathbf{x}|\boldsymbol{\pi}) = \sum_{n=1}^{N} \log \sum_{k=1}^{K} \pi_k \exp \left\{ (x^{(n)})^T \log(\mathbf{p}_k) + (1 - x^{(n)})^T \log(1 - \mathbf{p}_k) \right\}$$
(3.14)

¹(since we take the log, it will be a sum of the logs instead of the product of the elements)

 $^{^{2}}x^{n}$ are vectors, although not written bold

3.2 Question 3.(b)

We would like to find an expression for the responsibility of the mixture component k, denoted as $r_{n,k}$, for data vector $\mathbf{x}^{(n)}$. Using Bayes rule:

$$r_{n,k} = P(s^{(n)} = k | \mathbf{x}^{(n)}, \boldsymbol{\pi}, \mathbf{P}) = \frac{P(\mathbf{x}^{(n)} | s^{(n)} = k, \boldsymbol{\pi}, \mathbf{P}) P(s^{(n)} = k | \boldsymbol{\pi}, \mathbf{P})}{P(\mathbf{x}^{(n)} | \boldsymbol{\pi}, \mathbf{P})}$$
(3.15)

We notice that, since $s^{(n)}$ does not depend on **P**:

$$P(s^{(n)} = k | \boldsymbol{\pi}, \mathbf{P}) = P(s^{(n)} = k | \boldsymbol{\pi}) = \pi_k$$

And using the sum and product rules of probabilities, we get:

$$P(\mathbf{x}^{(n)}|\boldsymbol{\pi}, \mathbf{P}) = \sum_{i=1}^{K} P(\mathbf{x}^{(n)}, s^{(n)} = i|\boldsymbol{\pi}, \mathbf{P}) = \sum_{i=1}^{K} P(\mathbf{x}^{(n)}|s^{(n)} = i, \boldsymbol{\pi}, \mathbf{P}) \times P(s^{(n)} = i|\boldsymbol{\pi}, \mathbf{P})$$

Therefore, replacing in our expression, we get for the responsibility of mixture component k for data vector $\mathbf{x}^{(n)}$:

$$r_{n,k} = \frac{P(\mathbf{x}^{(n)}|s^{(n)} = k, \boldsymbol{\pi}, \mathbf{P}) \times P(s^{(n)} = k|\boldsymbol{\pi}, \mathbf{P})}{\sum_{i=1}^{K} P(\mathbf{x}^{(n)}|s^{(n)} = i, \boldsymbol{\pi}, \mathbf{P}) \times P(s^{(n)} = i|\boldsymbol{\pi}, \mathbf{P})}$$

$$r_{n,k} = \frac{\pi_k P(\mathbf{x}^{(n)}|s^{(n)} = k, \boldsymbol{\pi}, \mathbf{P})}{\sum_{i=1}^{K} \pi_i P(\mathbf{x}^{(n)}|s^{(n)} = i, \boldsymbol{\pi}, \mathbf{P})}$$
(3.16)

And since, using the E-step of the EM algorithm, we have:

$$P(\mathbf{x}^{(n)}|s^{(n)} = k, \boldsymbol{\pi}, \mathbf{P}) = \prod_{d=1}^{D} p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}}$$

Then:

$$r_{n,k} = \frac{\pi_k \prod_{d=1}^{D} p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}}}{\sum_{i=1}^{K} \pi_i \prod_{d=1}^{D} p_{i,d}^{x_d^{(n)}} (1 - p_{i,d})^{1 - x_d^{(n)}}}$$
(3.17)

Taking the log and naming R_k the expression in the numerator, we get:

$$R_k = \pi_k \prod_{d=1}^{D} p_{k,d}^{x_d^{(n)}} (1 - p_{k,d})^{1 - x_d^{(n)}}$$

$$\log R_k = \log \pi_k + \sum_{d=1}^{D} (x_d^{(n)} \log p_{k,d} + (1 - x_d^{(n)}) \log(1 - p_{k,d}))$$

And:

$$\log r_{n,k} = \log R_k - \log \left(\sum_{i=1}^K R_i\right) \tag{3.18}$$

3.3 Question 3.(c)

We would like to find the maximizing parameters for the expected log-joint with respect to parameters π and P. It can be expressed as:

$$\langle \sum_{n=1}^{N} \log P(\mathbf{x}^{(n)}, s^{(n)} | \boldsymbol{\pi}, \mathbf{P}) \rangle_{q(s^{(n)})} = \sum_{n=1}^{N} q(s^{(n)}) \log P(\mathbf{x}^{(n)}, s^{(n)} | \boldsymbol{\pi}, \mathbf{P})$$
(3.19)

Using conditional probabilities:

$$\log P(\mathbf{x}^{(n)}, s^{(n)} | \boldsymbol{\pi}, \mathbf{P}) = \log P(\mathbf{x}^{(n)} | s^{(n)}, \boldsymbol{\pi}, \mathbf{P}) + \log P(s^{(n)} | \boldsymbol{\pi}, \mathbf{P})$$

for which we already found the expression before (in question (b)) being:

$$\log P(\mathbf{x}^{(n)}, s^{(n)} | \boldsymbol{\pi}, \mathbf{P}) = \log R_k$$

$$\log P(\mathbf{x}^{(n)}, s^{(n)} | \boldsymbol{\pi}, \mathbf{P}) = \log \boldsymbol{\pi} + \sum_{d=1}^{D} (x_d^{(n)} \log p_{k,d} + (1 - x_d^{(n)}) \log(1 - p_{k,d}))$$
(3.20)

Or better in matrix and vector form:

$$\log P(\mathbf{x}^{(n)}, s^{(n)} | \boldsymbol{\pi}, \mathbf{P}) = \log \boldsymbol{\pi} + \sum_{d=1}^{D} \log(\mathbf{P})^{T} \mathbf{x}^{(n)} + \log(1 - \mathbf{P})^{T} (1 - \mathbf{x}^{(n)})$$

From before, we know the corresponding E-step in our case is:

$$q(s^{(n)}) = \mathbf{r}_n = [r_{n,1}, ..., r_{n,K}]^T$$

Resulting in the expression of E:

$$E = \sum_{n=1}^{N} \mathbf{r}_n \left(\log \boldsymbol{\pi} + \sum_{d=1}^{D} \mathbf{x}^{(n)} * \log(\mathbf{P})^T + (1 - \mathbf{x}^{(n)}) \log(1 - \mathbf{P})^T \right)$$
(3.21)

Maximizing the E-step:

$$\operatorname{argmax}_{\boldsymbol{\pi}, \mathbf{P}} \langle \sum_{n=1}^{N} \log P(\mathbf{x}^{(n)}, s^{(n)} | \boldsymbol{\pi}, \mathbf{P}) \rangle_{q(s^{(n)})}$$
(3.22)

Is equivalent to take the derivative of the expression of E and differentiate it with respect to π and \mathbf{P} and set the derivatives to 0.

Maximizing **P**, by finding the optimal $\hat{p}_{k,d}$:

$$\frac{\partial E}{\partial p_{k,d}} = \frac{\partial}{\partial p_{k,d}} \sum_{n=1}^{N} \mathbf{r}_n \left(\log \boldsymbol{\pi} + \sum_{d=1}^{D} \mathbf{x}^{(n)} \log(\mathbf{P})^T + (1 - \mathbf{x}^{(n)}) \log(1 - \mathbf{P})^T \right)$$

$$= \sum_{n=1}^{N} r_{n,k} \frac{\partial}{\partial p_{k,d}} \left(\log(p_{k,d}) x_d^{(n)} + \log(1 - p_{k,d}) (1 - x_d^{(n)}) \right)$$

$$\frac{\partial E}{\partial p_{k,d}} = \sum_{n=1}^{N} r_{n,k} \left(\frac{x_d^{(n)}}{p_{k,d}} + \frac{-(1 - x_d^{(n)})}{1 - p_{k,d}} \right) \tag{3.23}$$

And setting this equation to 0:

$$\frac{\partial E}{\partial p_{k,d}} = 0$$

$$\sum_{n=1}^{N} r_{n,k} \left(\frac{x_d^{(n)}}{\hat{p}_{k,d}} + \frac{-(1 - x_d^{(n)})}{1 - \hat{p}_{k,d}} \right) = 0$$

$$\frac{(1 - \hat{p}_{k,d}) \sum_{n=1}^{N} r_{n,k} x_d^{(n)} - \hat{p}_{k,d} \sum_{n=1}^{N} r_{n,k} (1 - x_d^{(n)})}{\hat{p}_{k,d} (1 - \hat{p}_{k,d})} = 0$$

$$\sum_{n=1}^{N} r_{n,k} x_d^{(n)} - \hat{p}_{k,d} \sum_{n=1}^{N} r_{n,k} x_d^{(n)} + \hat{p}_{k,d} \sum_{n=1}^{N} r_{n,k} x_d^{(n)} - \hat{p}_{k,d} \sum_{n=1}^{N} r_{n,k} = 0$$

$$\sum_{n=1}^{N} r_{n,k} x_d^{(n)} - \hat{p}_{k,d} \sum_{n=1}^{N} r_{n,k} x_d^{(n)} - \hat{p}_{k,d} \sum_{n=1}^{N} r_{n,k} = 0$$

$$\hat{p}_{k,d} = \frac{\sum_{n=1}^{N} r_{n,k} x_d^{(n)}}{\sum_{n=1}^{N} r_{n,k}}$$
(3.25)

Doing the same for π to find the optimal $\hat{\pi}_k$:

$$\frac{\partial E}{\partial \pi_k} = 0$$

However, this equation result leads to the sum over n of $r_{n,k}$ being equal to 0, because:

$$\frac{\partial E}{\partial \pi_k} = \sum_{n=1}^{N} \frac{r_{n,k}}{\pi_k}$$

This doesn't solve our problem. We must redefine this problem as an optimization problem where we want to maximize E subject to the constraint $\sum_k \pi_k = 1$. Using the Lagrangian multiplier λ to enforce normalization:

$$E_{Lagrangian} = E + \lambda \left(1 - \sum_{k=1}^{K} \pi_k \right) = 0$$
 (3.26)

And finding the conditions for stationarity:

$$\frac{\partial E_{Lagrangian}}{\partial \pi_k} = 0 \iff \sum_{n=1}^{N} \frac{r_{n,k}}{\hat{\pi}_k} - \lambda = 0$$

$$\sum_{n=1}^{N} r_{n,k} = \lambda \hat{\pi}_k$$

$$\hat{\pi}_k = \frac{\sum_{n=1}^{N} r_{n,k}}{\lambda}$$

$$\frac{\partial E_{Lagrangian}}{\partial E_{Lagrangian}} = 0 \iff \sum_{n=1}^{N} \frac{r_{n,k}}{\hat{\pi}_k} - \lambda = 0$$
(3.27)

And:

$$\frac{\partial E_{Lagrangian}}{\partial \lambda} = 0$$

Leads to:

$$\sum_{k=1}^{K} \pi_k = 1 \tag{3.28}$$

To find the parameter λ , we now replace in 3.28:

$$\sum_{k=1}^{K} \left(\frac{\sum_{n=1}^{N} r_{n,k}}{\lambda} \right) = 1$$

$$\lambda = \sum_{k=1}^{K} \sum_{n=1}^{N} r_{n,k} \tag{3.29}$$

Therefore, the final expression for the optimal $\hat{\pi}_k$ is:

$$\hat{\pi}_k = \frac{\sum_{n=1}^N r_{n,k}}{\sum_{k=1}^K \sum_{n=1}^N r_{n,k}} = \frac{\sum_{n=1}^N r_{n,k}}{\sum_{n=1}^N \sum_{k=1}^K r_{n,k}}$$

And since the sum over k of all the responsibilities $r_{n,k}$ is 1, then

$$\hat{\pi}_k = \frac{\sum_{n=1}^N r_{n,k}}{\sum_{n=1}^N 1*}$$

$$\hat{\pi}_k = \frac{1}{N} \sum_{n=1}^N r_{n,k}$$
(3.30)

3.4 Question 3.(d)

After implementing the EM algorithm for a mixture of K multivariate Bernoullis, the obtained results are displayed in the figures below (Figures 3.1 to 3.5), where the code was executed for $K \in \{2, 3, 4, 7, 10\}$. The initial value of π has been chosen as:

$$\boldsymbol{\pi} = \left[\frac{1}{\sum_{k} k}, ..., \frac{K}{\sum_{k} k}\right]$$

and for **P** were for each $p_{k,d}$ the mean values of $x_d^{(n)}$ (the same values were given on dimension k). We can see that for K = 10, the algorithm converges faster to a better value. This makes sense as there are 9 different single digits that can be drawn. The model would therefore find approximately a category for each, and one last category for the ones that were badly drawn.

A notable issue about it is the fact the optimization of the EM parameters only happened after around 5 to 10 iterations. We can suppose the model's performance depends on the initial values.

3.5 Question 3.(e)

In this section, we used the code from the previous questions and slightly modifying it (see the code following the figures below) to make it generate random initial parameters. The different initial random probabilities were normalized after being generated to still be valid probabilities.

In Figure ?? are displayed the initial random $p_{k,d}$ used in the EM algorithm. We can see there aren't any relevant pattern. Then, by running the algorithm on such initial values, we obtain the final parameters learned by the EM algorithm and displayed in Figure 3.11. The resulting parameters can be good for low dimensions (e.g. 3.6), but for larger dimensions, rapidly, it has learned parameters that do not look very good (with extreme probabilities, i.e. either 0 or 1). Comparing them to that of our fairly smart proposal (the data-driven one, shown in Figure 3.17) and by comparing both, it seems each category the data-driven look like a real handwritten digit.

We therefore conclude we got different solutions depending on the starting point. This algorithm therefore has some flaws, and the main flaw is its over-dependence on the data. By choosing the wrong data, the model won't be able to classify well the different categories of handwritten digits. From looking at the pictures, we also see it fails at finding clusters, since the handwritten digits are all similar in the different categories. Thus, overall, it would perform pretty badly in a real life scenario.

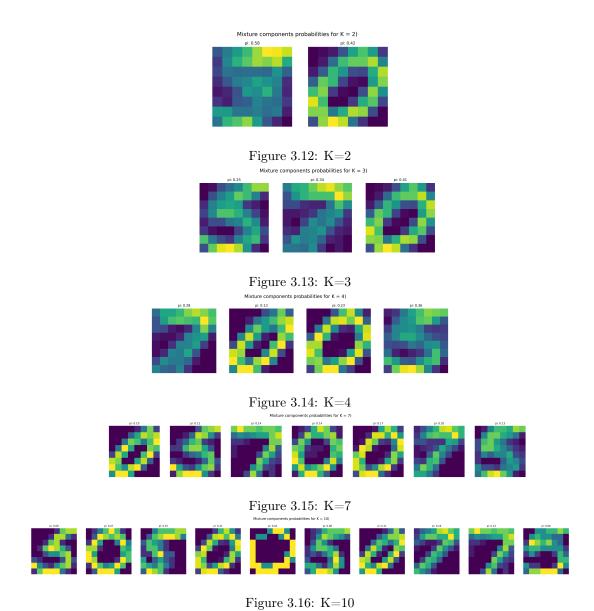

Figure 3.17: Parameters Learned by the EM Algorithm for Data-Driven Initialization

4 Question 5 - Decrypting Messages with MCMC

We are given an encrypted passage of English text. The mapping of this encryption is one-to-one, in a sense that all encrypted symbols are assigned to a unique other different symbol. The English text, composed of s_i symbols as $s_1s_2...s_n$, is modelled as a first-order Markov Chain:

$$p(s_1 s_2 ... s_n) = p(s_1) \prod_{i=2}^{n} p(s_i | s_{i-1})$$
(4.1)

4.1 Question 5.(a)

We define the transition probabilities in the studied text (i.e. "War and Peace", by Leo Tolstoy), as $p(s_i = \alpha | s_{i1} = \beta) = \psi(\alpha, \beta)$ and the stationary distributions of the symbols as $\lim_{i \to \infty} p(s_i = \gamma) = \phi(\gamma)$. We assume the first letter of the encrypted text is sampled from the stationary distributions.

The formulae for the ML estimates of $p(s_i = \alpha | s_{i-1} = \beta) = \psi(\alpha, \beta)$ are given by:

$$\psi_{ML}(\alpha, \beta) = \frac{\text{counts of pair } (\alpha, \beta) \text{ as } \beta \alpha \text{ in the text}}{\text{counts of symbol } \beta \text{ in the text}}$$

$$(4.2)$$

The stationary probabilities were calculated in the code by calculating, using the *np.linalg.eig()* function on the transpose of the transition probability matrix, finding the eigenvector corresponding to the eigenvalue with the value the closest to 1 and normalizing the values in that eigenvector by dividing them by their entire sum.

In Table 4.1, a few of the transition probability matrix are displayed. Since the table is too large, the csv file containing the whole matrix is joint to the report. In addition, Figure 4.1 shows the heat map plot corresponding to the matrix, which is clearer.

In Table 4.3 are displayed all the entries of the stationary distribution. In addition, the bar plot shown in Figure 4.2 shows the stationary distribution probabilities for each of the corresponding symbols.

Table 4.2: Stationary Probabilities

4.2 Question 5.(b)

We represent the mapping of s onto its corresponding encoding as $\sigma(s)$. We define each state of the MCMC sampler as a permutation between two mapping variables, meaning we simply exchange randomly the encoding of two distinct variables to their corresponding encoding symbols.

Assuming a uniform prior distribution over the permutations, we ask ourselves if the latent variables $\sigma(s)$ for different symbols s independent. The answer is no: the latent variables are not independent because assigning a latent variable to a symbol s reduces by one choice the possible assignment of the next latent variable to the next symbol s.

Let $e_1...e_n$ be an encrypted English text. We recall the equation (2.1), $p(s_1s_2...s_n) = p(s_1) \prod_{i=2}^n p(s_i|s_{i-1})$. Then relating them to the encoding function, the joint probability of $e_1...e_n$ given σ is:

$$e_i = \sigma(s_i) \iff s_i = \sigma^{-1}(e_i)$$

And thus:

$$p(e_1, ..., e_n, |\sigma) = \phi(\sigma^{-1}(e_1)) \prod_{i=2}^n p(\sigma^{-1}(e_i) | \sigma^{-1}(e_{i-1}))$$
(4.3)

4.3 Question 5.(c)

We use the Metropolis-Hastings algorithm with the proposal given by choosing two symbols s and s^2 at random and swapping the corresponding encrypted symbols.

The proposal probability $S(\sigma \to \sigma')$ depends on the permutations σ and σ' since we swap the encoding of two symbols in the mapping. Therefore, the proposal probability is the probability of choosing those two symbols simultaneously, given by:

$$S(\sigma \to \sigma') = \frac{1}{\binom{n}{2}} \tag{4.4}$$

where n is the number of symbols. In our case, we get:

$$S(\sigma \to \sigma') = \frac{1}{\binom{53}{2}} = \frac{2! \times 51!}{53!} = \frac{2}{53 \times 52}$$

$$S(\sigma \to \sigma') = \frac{1}{1378} \tag{4.5}$$

The MH acceptance probability, which depends on the current mapping (while the proposal probability did not) for a given proposal is given by:

$$A(\sigma' \rightarrow \sigma | e_1, ..., e_n) = \min \left(1, \frac{S(\sigma \rightarrow \sigma')p(\sigma' | e_1, ..., e_n)}{S(\sigma' \rightarrow \sigma)p(\sigma | e_1, ..., e_n)} \right)$$

We notice $S(\sigma' \to \sigma) = S(\sigma \to \sigma')$. Thus, we are left with:

$$A(\sigma \to \sigma'|e_1, ..., e_n) = \min\left(1, \frac{p(\sigma'|e_1, ..., e_n)}{p(\sigma|e_1, ..., e_n)}\right)$$

$$(4.6)$$

Recalling Bayes' Theorem:

$$p(\sigma|e_1, ..., e_n) = \frac{p(e_1, ..., e_n|\sigma)p(e_1, ..., e_n)}{p(\sigma)}$$

And similarly for σ ':

$$p(\sigma'|e_1,...,e_n) = \frac{p(e_1,...,e_n|\sigma')p(e_1,...,e_n)}{p(\sigma')} \iff p(e_1,...,e_n) = \frac{p(\sigma')p(\sigma'|e_1,...,e_n)}{p(e_1,...,e_n|\sigma')}$$

Combining the two expressions (by replacing $p(e_1, ..., e_n)$):

$$p(\sigma|e_1, ..., e_n) = \frac{p(e_1, ..., e_n|\sigma)}{p(\sigma)} \times \frac{p(\sigma')p(\sigma'|e_1, ..., e_n)}{p(e_1, ..., e_n|\sigma')}$$
(4.7)

And reinjecting them into the expression of A (equation (2.6)):

$$A(\sigma \to \sigma'|e_1, ..., e_n) = \min \left(1, \frac{p(\sigma'|e_1, ..., e_n)}{\frac{p(e_1, ..., e_n|\sigma)}{p(\sigma)} \times \frac{p(\sigma')p(\sigma'|e_1, ..., e_n)}{p(e_1, ..., e_n|\sigma')} \right)$$

$$= \min \left(1, \frac{1}{\frac{p(e_1, ..., e_n|\sigma)}{p(\sigma)} \times \frac{p(\sigma')}{p(e_1, ..., e_n|\sigma')} \right)$$

Leading to:

$$A(\sigma \to \sigma'|e_1, ..., e_n) = \min\left(1, \frac{p(e_1, ..., e_n|\sigma')p(\sigma)}{p(\sigma')p(e_1, ..., e_n|\sigma)}\right)$$

And since we assumed a uniform prior distribution over the permutations, then $p(\sigma) = p(\sigma')$ and therefore, the expression of the MH acceptance probability simplifies to:

$$A(\sigma \to \sigma'|e_1, ..., e_n) = \min\left(1, \frac{p(e_1, ..., e_n|\sigma')}{p(e_1, ..., e_n|\sigma)}\right)$$

$$\tag{4.8}$$

4.4 Question 5.(d)

This section's goal is to implement the MH sampler and running it on the encrypted text. In Table 4.3 are displayed the results every 100 iterations, using a random initial proposal, for the proposal encoding shown in 4.4.

4.5 Question 5.(e)

By definition, if a Markov Chain is ergotic, it can reach a unique steady-state, independent of the starting point. To be ergotic, a Markov Chain must be:

- 1) aperiodic, i.e. $P(X_n = s | X_{n-1} = s) = p_{s \to s} > 0$, implying it must also have a non-zero diagonal. In other words, it must be able to stay in every state with a non-null probability.
- 2) irreducible, *i.e.* if there is a path (with non-zero probability) from each state to every other state in the transition graph.

In our case, if there are some zero entries for $\phi(\alpha,\beta)$, then our distribution is not irreducible nor aperiodic, meaning $p_{s\to s}$ is not > 0. This makes sense since, in English, and especially in books such as War and Peace by Leo Tolstoy, there is a very low chance (if not a probability 0) to see a sequence of identical symbols (e.g. 'aaaaaaaa', 'bbbb', ...) for every symbol (53 in total). Moreover, these sequences of identical symbols must be seen much more than once for their probabilities to be non-negligible compared to other transitions and thus not to be neglected by the computer's precision, e.g. in the book's summary, the chapter titles XII, XIII, etc. introduce a transition probability between some letters, but it might not be sufficient enough since it happens a few times only in the whole book. Regarding the irreducibility of the chain, the same reason applies: states cannot be reached from all possible other states ('xyz' never happens a lot in a well-written book).

A possible solution to restore the ergodicity of the chain is to make the transition probabilities non-zero. For instance, we could set a threshold (e.g. ranging from 1e-8 to 1e-10), and correct all transition probabilities (including the diagonal elements) below that threshold to make them equal to the threshold. It must be done before calculating the stationary distributions. This will force back the ergodicity of the chain by permitting a restoration of both aperiodicity and irreducibility of the chain. However, this threshold must be low enough and have no incidence on the other symbols probability of occurring, because the only goal of the threshold is to restore ergodicity and not replace symbols we are sure of.

4.6 Question 5.(f)

As stated for the previous question, this method is not perfect for decoding, and there are flaws in the approach we will study.

The approach relies on analyzing how english words are formed to obtain a sequence of symbols making sense. Symbol probabilities alone won't be sufficient, we might obtain a sequence of spaces with a few of most-used letters in the english language (a, e, etc.), and there might even be no letters at all since the space probability is very high compared to them. The sequences of symbols won't make sense and the program won't fulfill the initial task, a sufficient reason to refute this idea.

Using a second-order Markov chain can introduce some computation issues, because the program will have to work in three dimensions for transition probabilities (one for each symbol s_i, s_{i-1} and s_{i-2}). This makes the computation much more complex because the transition probability matrix will have $N \times N \times N$ in addition to a third dimension. Since eigenvalues are calculated for 2D matrices, we might also have to adapt the code to fit 3D eigenvalues/eigenvectors methods. An additional information to refute this idea of second-order Markov chain is the fact the training data must be much higher for the model to be as accurate as a first-order Markov Chain.

If the encryption scheme allows two symbols to be mapped to the same encrypted value, the approach will simply first attribute spaces, and then decrypt the most used word in the training set that has the same number of letters. We will obtain a sentence which won't make sense, and thus it will not decrypt the message as intended. Or we could even simply have a sequence of random spaces and letters, since

only depending on stationary distributions.

If we use the approach on Chinese language for instance, it his highly probable the program won't be able to decrypt the message. Firstly, this is because Chinese signs are unique and don't work as english and other western languages where letters and symbols represent how we pronounce the word. Chinese language associates images (each having a full meaning alone) to each symbol, which makes their use much less frequent in sentences than letters in english and will be much more complicated for the computer to grasp. For example, if the sentence to decrypt is "The dog eats outside.", the computer won't make the difference between "cat" and "dog", between "eating" and "playing", etc. It will likely decrypt the wrong sentence. Additionally, their transition probabilities and stationary probabilities might end up to be very low values, which will be harder for the program to decrypt. Using a two-symbol swap as we did in the approach is also too low, and the time for the program to decrypt the language will be too higher. Hence, to resume what will happen knowing all this information: the program will offer a two symbol swap; the difference in probability will be so low, that they will most likely be rejected during the acceptance step of the Metropolis-Hasting algorithm. We will end-up in an infinite loop.

A remark we can make when displaying the whole decrypted message is the fact some letters still can't be decrypted right by the program since they are not very used (e.g. j, q, z, k and probably x), even after a high number of iterations. What we can see in common for these letters is their very low stationary probabilities. Their probabilities are somehow lower or equal to punctuation probabilities. We could also apply the threshold method to the stationary vector, but I doubt it will solve the issue, because they might have an impact on highly-probable symbols by replacing them where they were expected.

5 Question 7 - Optimization

5.1 Question 7.(a)

We want to find the local extrema of the function f(x,y) = x + 2y subject to the constraints $y^2 + xy = 1$. This is a constrained optimization problem, with an equality constraint.

We name $g(x,y) = y^2 + xy - 1$, where finding the values of x and y such that g(x,y) = 0 is a reformulation of the constraint of our problem. Introducing a Lagrange multiplier, denoted by λ , the problem is equivalent to solving the following system of equations:

$$\begin{cases}
\nabla f(x,y) + \lambda \nabla g(x,y) = 0 & (E_1) \\
g(x,y) = 0 & (E_2)
\end{cases}$$
(5.1)

 ∇f and ∇g are in three dimensions, one for each of the following variables: x, y, λ . Differentiating with respect to each variables the equations, we get:

$$\frac{\partial E_1}{\partial x} = 0 \quad \Longleftrightarrow \quad \frac{\partial}{\partial x} \left(x + 2y + \lambda (y^2 + xy - 1) \right) = 0 \quad \Longleftrightarrow \quad \lambda y + 1 = 0 \tag{5.2}$$

Calculated a similar manner:

$$\frac{\partial E_1}{\partial y} = 0 \quad \Longleftrightarrow \quad 2 + 2\lambda y + \lambda x = 0 \tag{5.3}$$

$$\frac{\partial E_1}{\partial \lambda} = 0 \quad \Longleftrightarrow \quad y^2 + xy - 1 = 0 \tag{5.4}$$

Thus:

$$\begin{cases} \lambda y + 1 = 0\\ 2 + 2\lambda y + \lambda x = 0\\ y^2 + xy - 1 = 0 \end{cases}$$

$$(5.5)$$

Equivalent to:

$$\begin{cases} \lambda = -\frac{1}{y} \\ 2 + 2\left(-\frac{1}{y}\right)y + (-\frac{1}{y})x = 0 \\ y^2 + xy - 1 = 0 \end{cases} \begin{cases} \lambda = -\frac{1}{y} \\ -\frac{x}{y} = 0 \\ y^2 + xy - 1 = 0 \end{cases} \begin{cases} \lambda = -\frac{1}{y} \\ x = 0 \\ y^2 - 1 = 0 \end{cases}$$

We obtain as results $y=\pm 1,\ x=0,\ \text{and}\ \lambda=\mp 1.$ Thus, we obtained the solutions to the system and to the optimization problem, *i.e.* the locations of the local extrema:

$$(x,y) \in \mathcal{S} = \{(0,1), (0,-1)\}\$$

5.2 Question 7.(b)

We assume we dispose of a method to evaluate the exponential function $\exp(x) = e^x$. We would like to evaluate the function $\ln a$, for a given $a \in \mathbb{R}_+$ using Newton's method.

5.2.1 Question 7.(b).(i)

Firstly, we can recall the exponential function's inverse mapping is the logarithmic function, *i.e.* $\exp(\ln x) = x$, and we can additionally write $\exp^{-1}x = \ln x$.

Thus, we can use the following function f(x, a) to which Newton's Method can be applied to x such that $x = \ln a$:

$$f(x,a) = e^x - a (5.6)$$

And by solving the equation f(x, a) = 0, we obtain the logarithm of a, *i.e.* $\ln a$.

5.2.2 Question 7.(b).(ii)

The update equation in Newton's method to search for the root of f, f(x, a) = 0, is found using the following formula:

$$x_{n+1} = x_n - \frac{f(x_n, a)}{f'(x_n, a)}$$
(5.7)

Calculating the first derivative of f with respect to x_n :

$$f'(x_n, a) = \frac{\partial (e^{x_n} - a)}{\partial x_n}$$
$$f'(x_n, a) = e^{x_n}$$
 (5.8)

Therefore, we obtain:

$$x_{n+1} = x_n - \frac{e^{x_n} - a}{e^{x_n}} \iff x_{n+1} = x_n - 1 + \frac{1}{e^{x_n}}$$
 (5.9)

6 Question 8 - [BONUS] Eigenvalues as solutions of an optimization problem

We define A as a symmetric $n \times n$ - matrix, and:

$$q_A(x) = x^T A x$$
 and $R_A(x) = \frac{q_A(x)}{||x||^2} = \frac{x^T A x}{x^T x}$ for $x \in \mathbb{R}^n$. (6.1)

We remind the purpose of this problem is to verify the fact: If A is a symmetric $n \times n$ -matrix, the optimization problem $x^* = \arg\max_{x \in \mathbb{R}^n} R_A(x)$ has a solution, $R_A(x^*)$ is the largest eigenvalue of A, and x^* is a corresponding eigenvector.

6.1 Question 8.(a)

The Extreme Value theorem states the following:

If a function f is continuous on a closed interval [a; b], then f attains both a maximum and a minimum in that interval.

i.e.
$$\exists x_{max} \in [a;b] / \forall x \in [a;b] f_{max} \ge f(x)$$
 (6.2)

$$\exists x_{min} \in [a; b] \quad / \quad \forall x \in [a; b] f_{min} \le f(x)$$

$$(6.3)$$

The conditions for the validity of such theorem are requirements int he function f that f should be both **continuous** and **defined on a closed interval** (the function must be "compact").

We would like to show that $\sup_{x \in \mathbb{R}^n} R_A(x)$ using the extreme value theorem. Firstly, since \mathbb{R}^n is not compact, we need to find an interval of definition to be compact while having an equivalent supremum. Let's prove the unit sphere $S = \{x \in \mathbb{R}^n | ||x|| = 1\}$, which is a compact set, has an equivalent supremum.

Then, defining $s \in \mathbb{R}^n$, we notice $\forall s \in \mathbb{R}^n, \exists x \in \mathbb{S} \ / \ x = \frac{s}{\|s\|}$. This expression is true, because by dividing by the norm of each vector in the space \mathbb{R}^n , we obtain a unit vector comprised in the interval S. By replacing in $R_A(x)$'s expression, we get:

$$\sup_{\{x \in S\}} R_A(x) = \sup_{\{x \in \mathbb{R}^n | \|x\| = 1\}} \frac{x^T A x}{x^T x}$$

$$= \sup_{\{\frac{s}{\|s\|} \in \mathbb{R}^n | \|\frac{s}{\|s\|}\| = 1\}} \frac{\left(\frac{s}{\|s\|}\right)^T A \frac{s}{\|s\|}}{\left(\frac{s}{\|s\|}\right)^T \frac{s}{\|s\|}}$$

$$= \sup_{\{\frac{s}{\|s\|} \in \mathbb{R}^n | \|\frac{s}{\|s\|}\| = 1\}} \frac{\frac{s^T}{\|s\|} A \frac{s}{\|s\|}}{\frac{s^T}{\|s\|}}$$

And since ||s|| is a scalar:

$$= \sup_{\left\{\frac{S}{\|s\|} \in \mathbb{R}^{n} | \left\|\frac{s}{\|s\|}\right\| = 1\right\}} \frac{\frac{s^{T}}{\|s\|^{2}} A s^{T}}{\frac{s^{T}s}{\|s\|^{2}}}$$

$$= \sup_{\left\{\frac{S}{\|s\|} \in \mathbb{R}^{n} | \left\|\frac{s}{\|s\|}\right\| = 1\right\}} \frac{s^{T} A s}{s^{T} s}$$

And switching back to the domain of definition of s, since the :

$$= \sup_{\left\{s \in \mathbb{R}^n\right\}} \frac{\frac{s^T}{\left\|s\right\|^2} A s^T}{\frac{s^T s}{\left\|s\right\|^2}}$$
$$= \sup_{\left\{s \in \mathbb{R}^n\right\}} R_A(s)$$

Leading to the final expression of:

$$\sup_{x \in S} R_A(x) = \sup_{s \in \mathbb{R}^n} R_A(s) \tag{6.4}$$

Which proves the supremum of the set $S = \{x \in \mathbb{R}^n | ||x|| = 1\}$ is equivalent to that of \mathbb{R}^n .

Since the set S is continuous (because its expression, the unit sphere, is valid for all element of \mathbb{R}^n), and is bounded (its images limits are finite numbers, *i.e.* all equal to 1), then the **Extreme Value theorem applies** to our case and therefore, the supremum of $R_A(x), x \in \mathbb{R}^n$ is attained when the supremum of $R_A(x_s), x_s \in S$ is attained.

6.2 Question 8.(b)

We define $\lambda_1 \geq ... \geq \lambda_n$ as the eigenvalues of A in descending order, and $\xi_1, ..., \xi_n$ their corresponding eigenvectors that form an ONB.

Using our previous results, we start from the unit sphere:

$$\sup_{x \in \mathbb{R}^n | \|x\| = 1} \frac{x^T A x}{\|x\|} = \sup_{x \in \mathbb{R}^n | \|x\| = 1} x^T A x \tag{6.5}$$

For all $x \in \mathbb{R}^n$, we can rewrite using A's eigenvectors (since they form an ONB) as:

$$x = \sum_{i=1}^{n} (\xi_i^T x) \xi_i \tag{6.6}$$

Thus, replacing in our problem, we get:

$$x^{T} A x = \left(\sum_{i=1}^{n} (\xi_{i}^{T} x) \xi_{i}\right)^{T} A \left(\sum_{i=1}^{n} (\xi_{i}^{T} x) \xi_{i}\right) = \left(\sum_{i=1}^{n} ((\xi_{i}^{T} x) \xi_{i})^{T}\right) A \sum_{i=1}^{n} (\xi_{i}^{T} x) \xi_{i}$$

If we recall the following property of eigenvectors of the matrix A:

$$A\xi_i = \lambda_i \xi_i$$

Then since A is symmetric, the property is valid for the transpose of eigenvectors:

$$A\xi_i^T = \lambda_i \xi_i^T$$

Therefore:

$$x^{T} A x = \left(\sum_{i=1}^{n} ((\xi_{i}^{T} x) \xi_{i})^{T}\right) \sum_{i=1}^{n} A \xi_{i}^{T} x \xi_{i} = \left(\sum_{i=1}^{n} ((\xi_{i}^{T} x) \xi_{i})^{T}\right) \sum_{i=1}^{n} \lambda_{i} \xi_{i}^{T} x \xi_{i}$$

Using the property of transpose:

$$(AB)^T = B^T A^T$$

Then:

$$x^{T}Ax = \left(\sum_{i=1}^{n} \xi_{i}^{T} (\xi_{i}^{T}x)^{T}\right) \sum_{i=1}^{n} \lambda_{i} \xi_{i}^{T} x \xi_{i} = \left(\sum_{i=1}^{n} \xi_{i}^{T} x^{T} (\xi_{i}^{T})^{T}\right) \sum_{i=1}^{n} \lambda_{i} \xi_{i}^{T} x \xi_{i}$$

$$= \left(\sum_{i=1}^{n} \xi_{i}^{T} x^{T} \xi_{i}\right) \sum_{i=1}^{n} \lambda_{i} \xi_{i}^{T} x \xi_{i}$$

$$x^{T}Ax = \left(\sum_{i=1}^{n} \xi_{i}^{T} x^{T} \xi_{i}\right) \left(\lambda_{i} \sum_{i=1}^{n} \xi_{i}^{T} x \xi_{i}\right)$$

$$(6.7)$$

Since λ_i is a scalar.

And, since ξ_i , $i \in \{1, ..., n\}$ form an orthonormal basis (ONB), then:

$$\xi_i^T \xi_j = \begin{cases} 1, & i = j \\ 0, & i \neq j \end{cases}$$
 (6.8)

Thus:

$$x^T A x = \sum_{i=1}^n \lambda_i \xi_i^T x^T x \xi_i$$

$$x^T A x = \sum_{i=1}^n \lambda_i x_i^T \xi_i$$

And once again using the property of the ONB vectors 6.8, then:

$$x^T A x = \sum_{i=1}^n \lambda_i \tag{6.9}$$

Since we defined the eigenvalues of A previously as $\lambda_1 \geq ... \geq \lambda_n$ in descending order, then:

$$R_A(x \in S) = \sum_{i=1}^n \lambda_i \le \lambda_1 \tag{6.10}$$

Which was what we intended to prove.

6.3 Question 8.(c)

We consider $x \in \mathbb{R}^n \setminus \{\xi_1, ..., \xi_k\}$, which means all x in \mathbb{R}^n that is not a part of $\{\xi_1, ..., \xi_k\}$. The $\{\xi_1, ..., \xi_k\}$ contains all the linear combinations of linearly independent eigenvectors corresponding to $\lambda_1, k \leq n$.

Therefore, x can be rewritten as we did before for Question 8.(b), but excluding all the eigenvectors corresponding to λ_1 :

$$x = \sum_{i=k+1}^{n} (\xi_i^T x) \xi_i$$
 (6.11)

Using our previous result for Question 8.(b), we can state (remembering the eigenvalues are ordered in descending order and thus λ_{k+1} is the maximum):

$$R_A(x) = x^T A x = \sum_{i=k+1}^n \lambda_i \le \lambda_{k+1}$$

And since $\lambda_{k+1} < \lambda_1$, then:

$$R_A(x) < \lambda_1 x \in \mathbb{R}^n \setminus \operatorname{span}\{\xi_1, \dots \xi_k\}$$
 (6.12)

Which is what we needed to prove.
